

To Session or not to Session

Session Concepts in Currently Emerging Future Networks

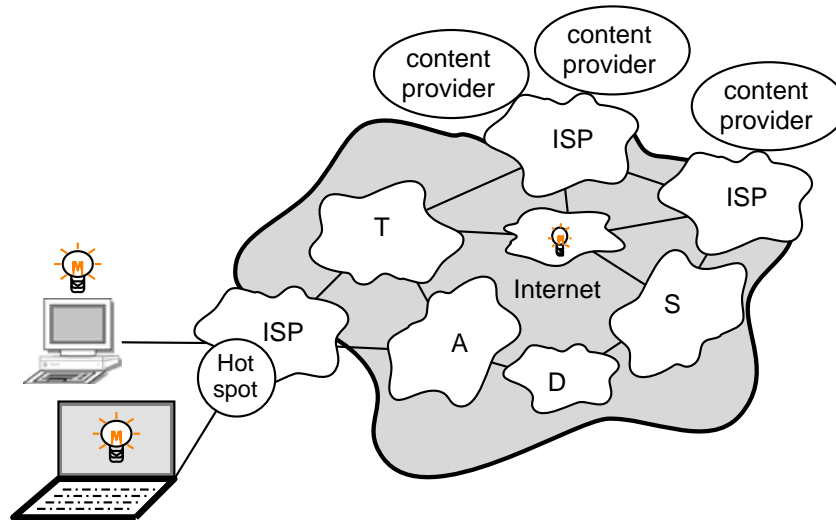

Michael Scharf, Marc Necker,
C. Gauger, B. Gloss, C. Hauser, J. Jähnert, S. Kiesel,

6th Würzburg Workshop on IP: "Visions of Future Generation Networks"
August 1, 2006

- Outline:**
- To session in general
 - Pros and cons of sessioning
 - To session in particular

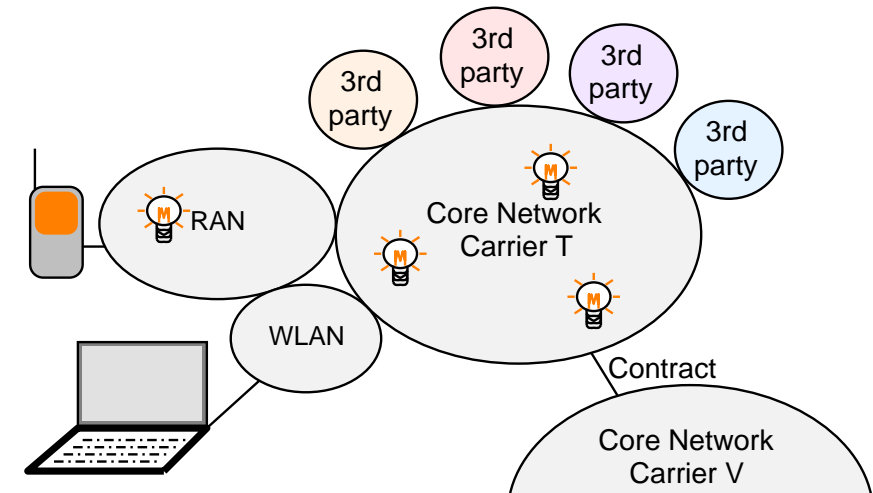

Traditional Network Design Principles

Internet

- **End-to-end argument: Intelligence is located in the end-nodes**
- **ISP provides bitpipe only**
- **Open to many new services**
- ➔ **User centric design**

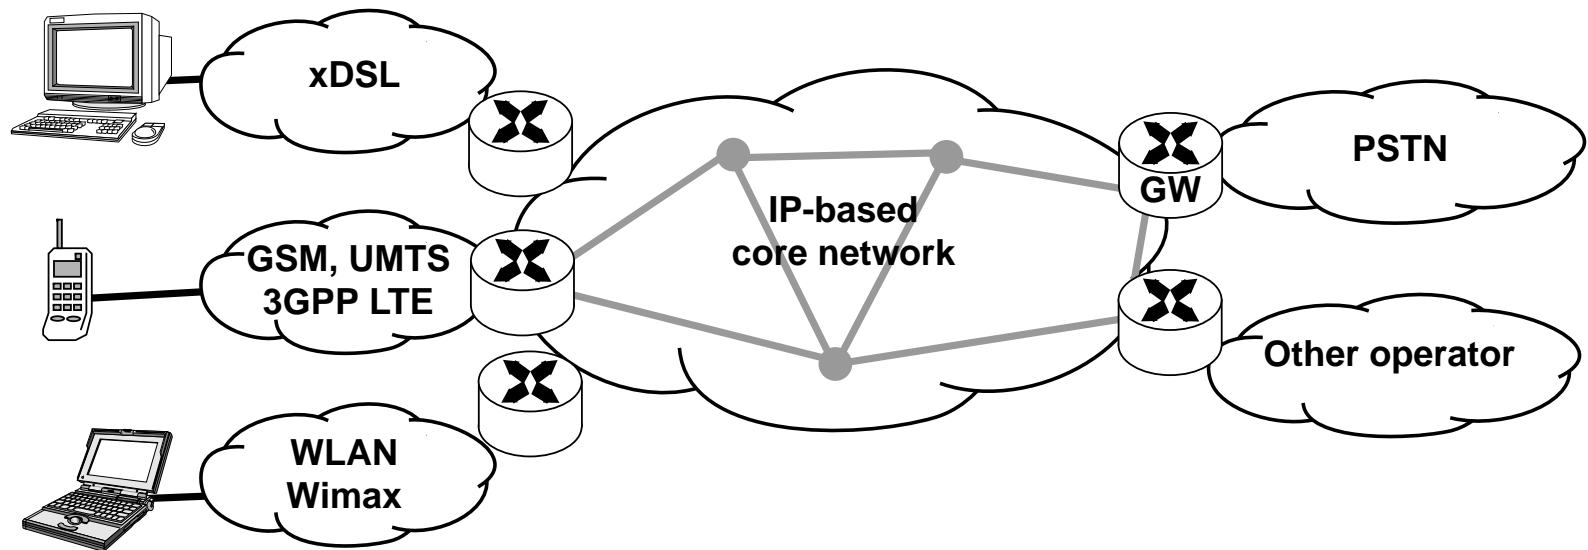

Telecommunication networks

- **Operator control: Intelligence is located in the network**
- **Closed network, usage-based charging**
- **Well-standardized services**
- ➔ **Operator driven / network centric**

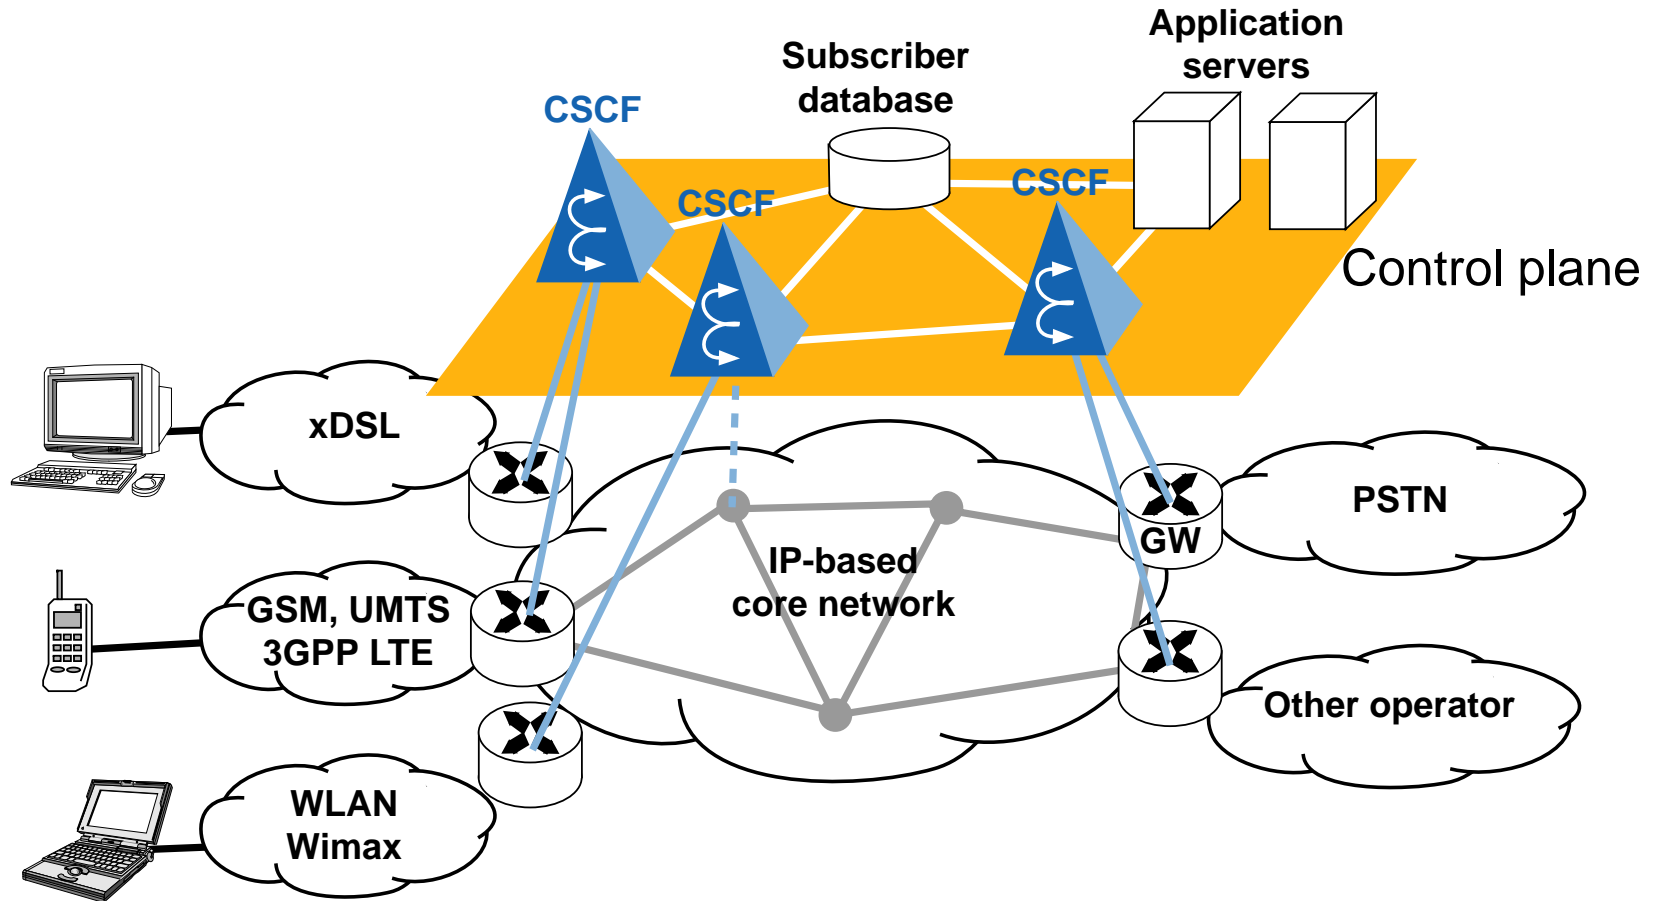

Current Trends

Pros and Cons of State in the Network

↳ **Reasons beyond QoS!**

Mobility Management

- **Mobile IP: End-to-end solution**

Mobility Management

- **Mobile IP: End-to-end solution**
- **Cellular networks: Highly stateful**

Resource Management

- **Challenge: Common resource management for heterogeneous networks**
- **Needs to be network driven, or at least network assisted**
- ➔ **Optimal resource management requires session information**

state
needed

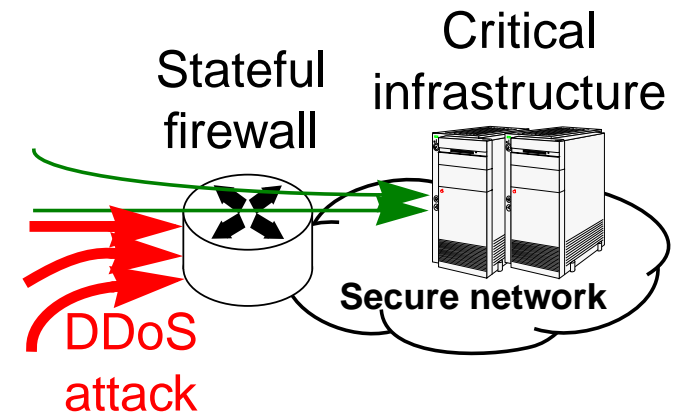

Research Issues

- **Architectures and protocols for holistic resource management**
- **Mobility management across heterogeneous access networks**
- **Cross-layer indications (e. g., for adaptive applications)**

state
needed

Distributed Denial-of-Service Attacks (DDoS)

- **Serious problem in today's Internet**
- **DDoS countermeasures**
 1. Massive overprovisioning and replication (e. g., content delivery networks)
 2. Protection by packet filters and firewalls
- **Possible solution: Per-flow access control by firewalls** **state needed**
 - Packet filters or firewalls at domain boundaries
 - Blacklist or whitelist approach possible

Research Issues

- Interaction with session signaling protocols (e. g., SIP)
- "Path-coupled" vs. "path-decoupled" firewall signaling

Problem 1: Topology Hiding

- Non-disclosure of internal network details
- Requirement by operators
- Signaling filtering **state needed**
- Research issue: Interdomain-operation with limited knowledge

Problem 1: Topology Hiding

- Non-disclosure of internal network details
- Requirement by operators
- Signaling filtering **state needed**
- Research issue: Interdomain-operation with limited knowledge

Problem 2: User Location Privacy

- Hiding of sensible user data (e. g., IP address)
- Address mapping, e. g., by network address port translation (NAPT), JAP
- Requires session state at intermediary anonymizers **state needed**
- "Feature": May prevent end-to-end communication by users (P2P)
- Research issue: Interworking with end-to-end protocols

Problem 3: Anonymity

- **Usual trust model: Network operator is fully trusted**
 - But: Aggregation of knowledge at operator raises privacy issues
 - More and more operators and service providers
 - Internet does not only span democratic countries
- **Anonymity can be achieved by encryption and multiple anonymizers**

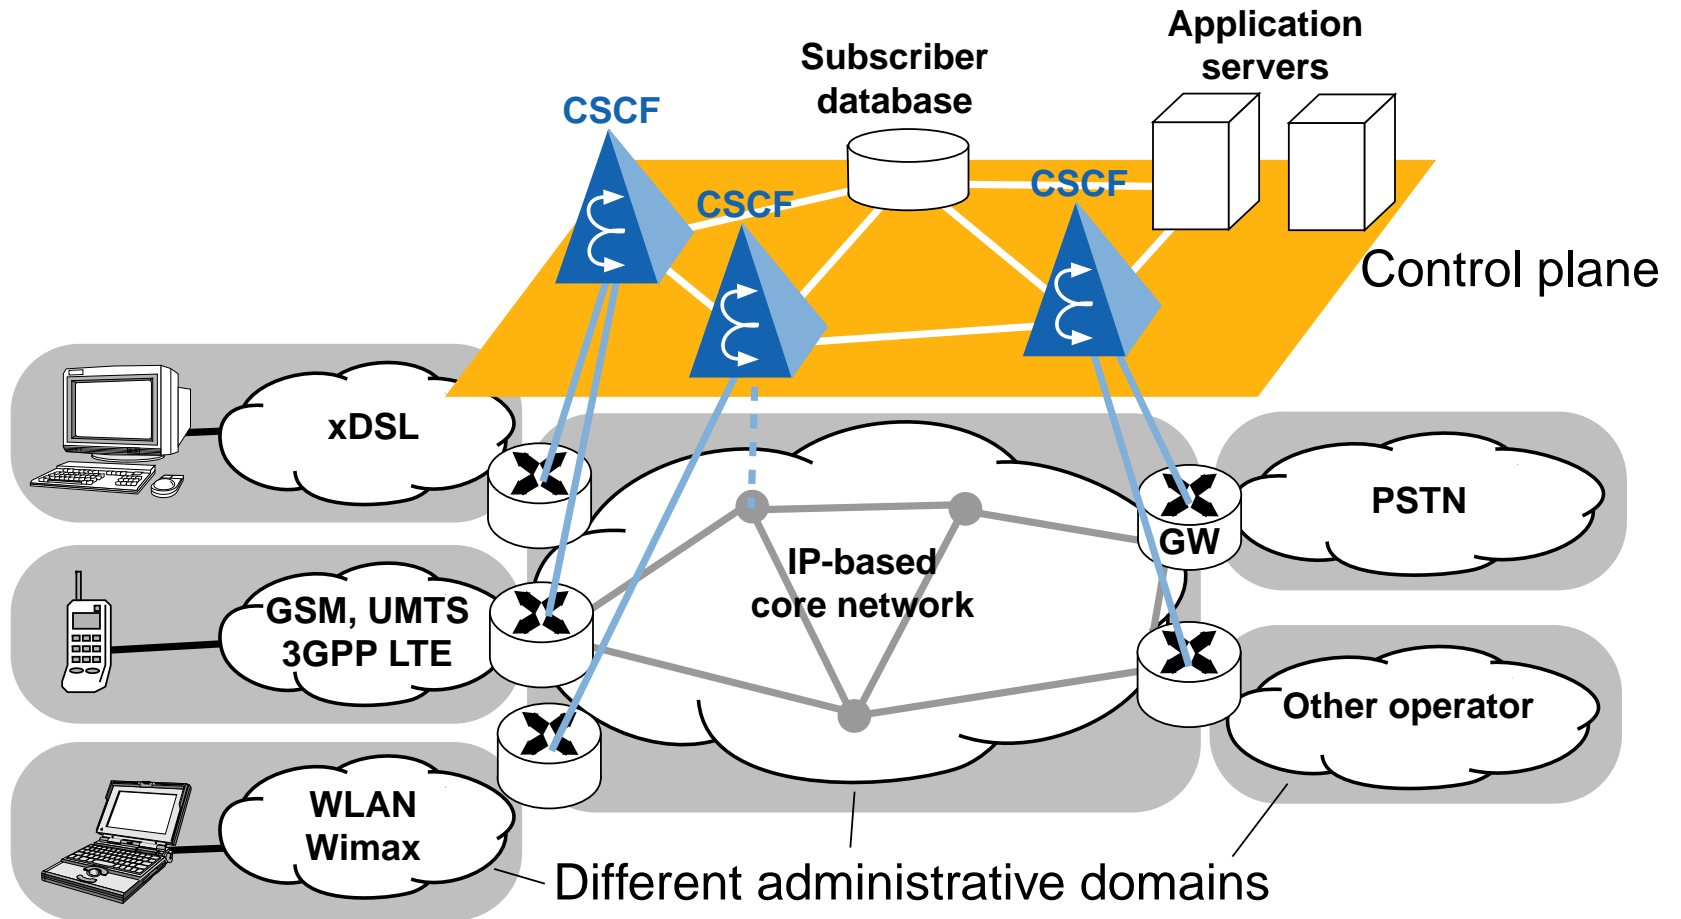

- **Information is encoded in packets, no state in anonymizers**
- **Research issue: Preventing inference by cooperation, ...**
- ➔ **Protection of user *against network operator***

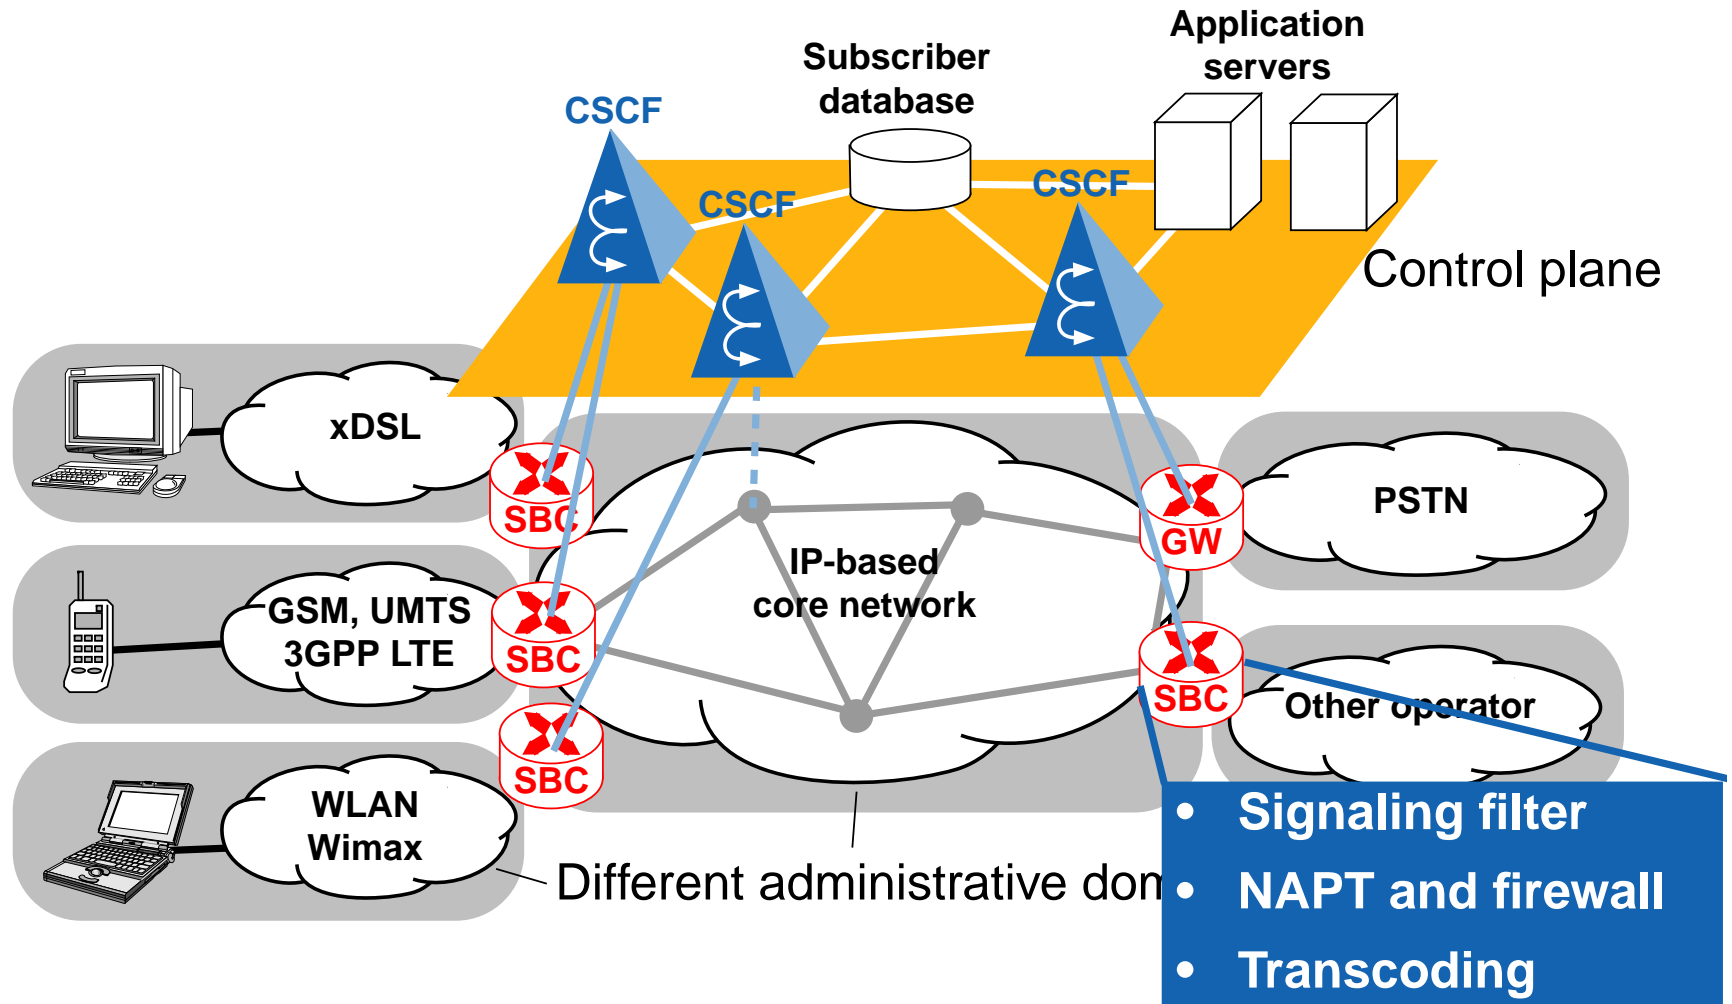

Future Generation Networks

The Raise of ...

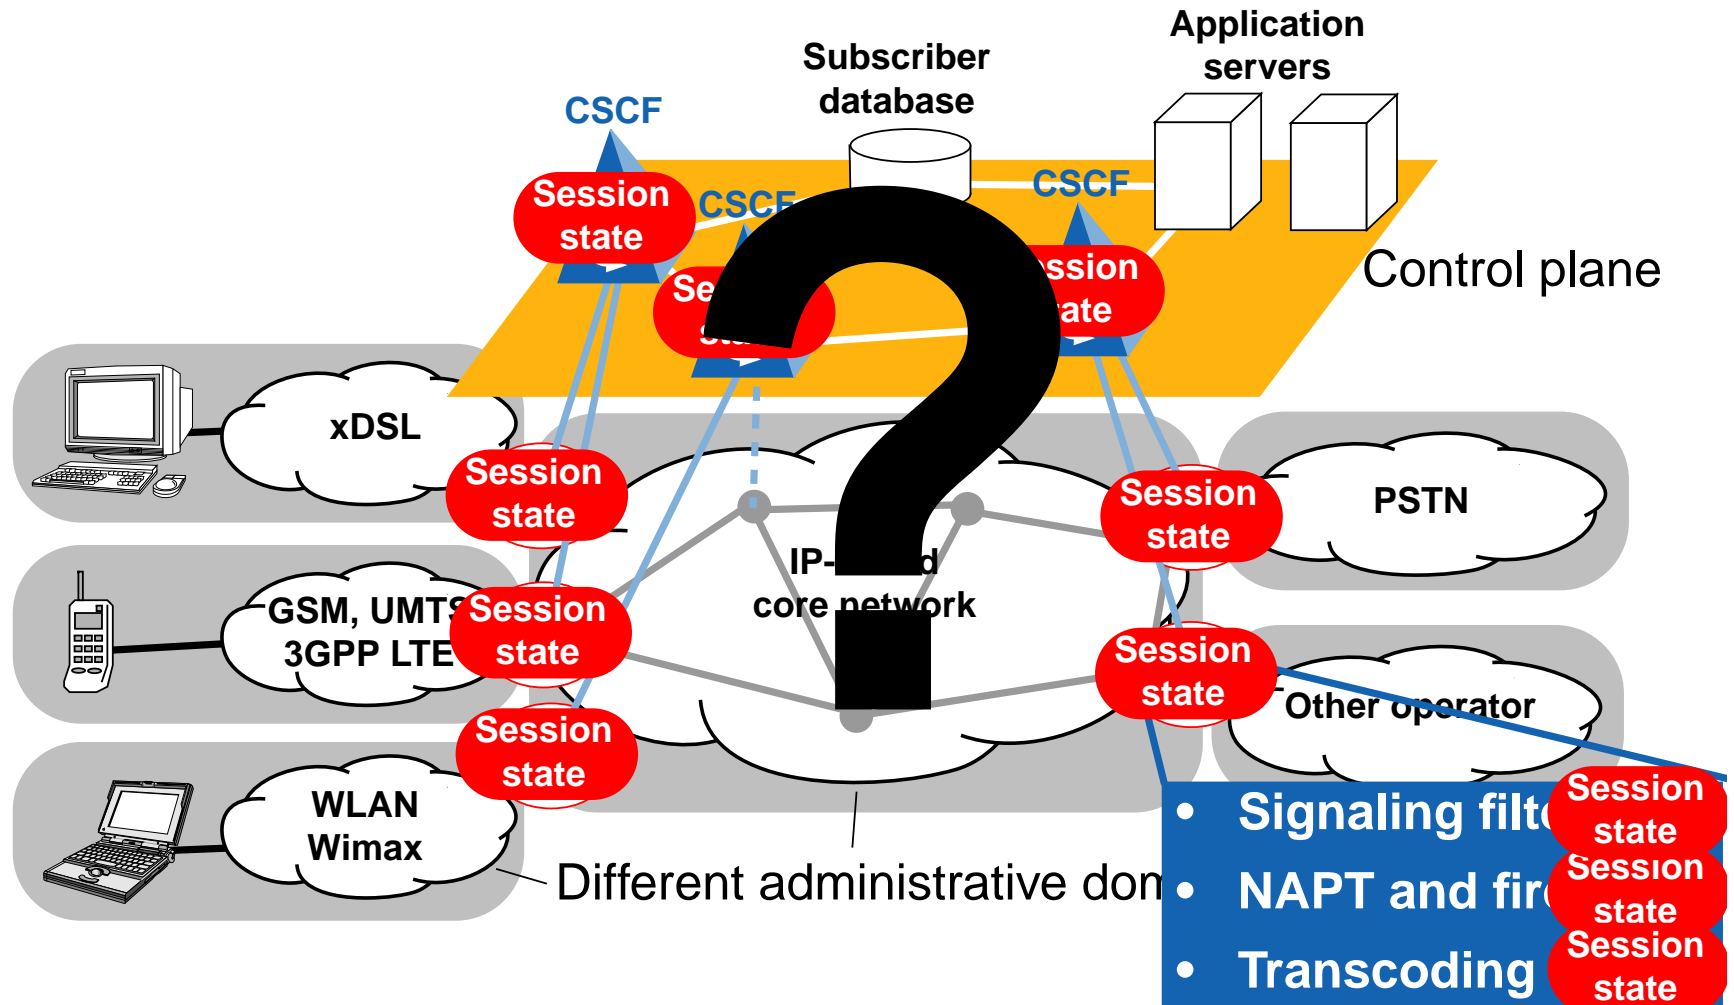

Future Generation Networks

The Raise of Session Border Controllers (SBC)

Future Generation Networks

The Raise of Session Border Controllers (SBC)?

➔ IMS/TISPAN/... as "one-does-it-all" solution?

Conclusion
